**Abstract**—Gender recognition from facial images has become an empirical aspect in present world. It is one of the main problems of computer vision and researches have been conducting on it. Though several techniques have been proposed, most of the techniques focused on facial images in controlled situation. But the problem arises when the classification is performed in uncontrolled conditions like high rate of noise, lack of illumination, etc. To overcome these problems, we propose a new gender recognition framework which first preprocess and enhances the input images using Adaptive Gamma Correction with Weighting Distribution. We used Labeled Faces in the Wild (LFW) database for our experimental purpose which contains real life images of uncontrolled condition. For measuring the performance of our proposed method, we have used confusion matrix, precision, recall, F-measure, True Positive Rate (TPR), and False Positive Rate (FPR). In every case, our proposed framework performs superior over other existing state-of-the-art techniques.

**Index Terms**— Contrast Enhancement, Gender Recognition, Feature Extraction, Classification, Preprocessing

## I. INTRODUCTION

Nowadays gender recognition from facial image has become an active research area in the field of computer vision for different applications such as biometric authentication, surveillance systems, market analysis, security systems, etc. Gender can be recognized in different ways such as from human body shape, gait component [29], facial image [3-15, 28], etc. There have been a number of gender recognition approaches but none of these able to provide satisfactory result in some uncontrolled situations. Moreover, some facial images are so confusing that most of the time human beings fail to recognize gender from facial images. Fig.1 represents some such types of image which are taken from LFW database [17]. So, there is a wide scope of improving the performance of gender recognition approaches. This paper presents a novel approach for gender recognition from facial images.

Fig. 1. Real life confusing image (a) male but looks like female, (b) female but looks like male

Gender recognition from facial image can be broadly categorized into two groups such as appearance-based approach and feature-based approach. Appearance-based approach uses the global feature of the whole face image as an attribute for classification whereas feature-based approach uses a set of discriminative facial features such as nose, eye-brow, cheek, etc which are extracted from facial image as classification attributes. Most of the time the male faces have prominent nose, eye-brow over the female faces and on the contrary the female faces have clear cheeks. Moreover, regions of nose and chin show a greatest difference between male and female faces [15].

Lapedriza *et al.* [8] classified facial features into two parts such as internal and external. Eyes, nose and mouth were considered as internal parts in where hair, chin and

ears were taken as the external part. Noteworthy, the more essential information can be gained from external facial portion. For their experimental purpose, they used FRGC database. Baluja *et al.* [10] proposed a boosting sex identification performance method in where gender recognition is performed based on boosting pixel comparison. They used FERET database and SVM on images of 20×20 pixels. Makinen *et al.* [11] proposed a gender recognition method by considering FERET database. All of the above studies have some universal problems because they used FERET database in where images are captured under controlled situation such as frontal faces, consistent lighting, etc. However, it is almost impractical to capture images in real time gender recognition applications in controlled situation due to

lack of sunlight, pose variation, presence of the cloud, variation of illumination, image capturing devices, etc [30]. So, real time gender classification is a challenging issue and has increased demand in day by day. Though few methods have been proposed for recognizing gender from real life images, the performance is not as satisfactory as desired.

Concerning of real time gender recognition Shakhnarovich *et al.* [13] took over 3,500 facial images from websites which are more challenging to recognize. The authors achieved 79.0% accuracy using Haar-like features with Adaboost and 75.5% accuracy using Haar-like features with SVM. Caifeng Shan [14] also made an investigation on gender recognition using 7,443 real-life face images from LFW database which is captured in uncontrolled situation. The author used boosted LBPH features with SVM and claimed for 94.81% accuracy. Though the author used LFW database, he did not consider 5,790 difficult face images which are captured in uncontrolled situation. Dey *et al.* [15] tried to remove noise from facial image using Histogram Equalization

(HE). But in some situations over enhancement caused by HE removes some important features from a face image [1]. Fig.2 represents the over enhancement effect of HE on images of LFW database. The authors experiment over 4,000 facial images using LBP features with DCT and obtained 79% accuracy.

Fig. 2. Problem of histogram equalization (a) Original images, (b) Images after applying HE

Table 1. Several Existing Gender Classification Techniques and their Recognition Rate

| Ref. | Features              | Data set       | No. of Samples | Classifier    | Result (%) |

In this paper, we have used the LFW cropped [17] database for our experimental purpose on real-life facial images. As real life images are captured in uncontrolled situation, it may contain noises. Features may not be clearly visualized which is responsible for failure in successful recognition. So, preprocessing is the first step to remove noise from the facial image. Many local feature based approaches are proposed for feature extraction from facial image such as local binary pattern (LBP) [18], local ternary pattern (LTP) [25], local gradient Pattern (LGP) [24], etc. The Adaboost algorithm is adjusted by Tieu and Viola [23] for image analysis. A low contrasted image or a noisy image may lose the detail information or important characteristics which help to differentiate male and female gender. As a result, real time gender classification has become difficult. To mitigate this problem we proposed a framework whose first step is to noise filtering and contrast enhancement. Noise reduction can be done in several ways. Different image contrast enhancement techniques can be employed. But some of the techniques have some over-enhancement effect which may obsolete detail information of the image. Along with this artifacts can be occurred as well. Among all of the contrast enhancement and noise filtering techniques, we use Adaptive Gamma Correction with Weighted Distribution (AGCWD) technique to reduce the noise and clearly visualize detail information.

Rest of the paper is structured as follows. In Section II, we describe our proposed gender recognition technique. Section III presents our extensive experiments and, Section IV contains concluding statements.

## II. PROPOSED METHOD

Gender recognition broadly depends on face detection, feature extraction and classification. We have used the cropped LFW database which contains only the facial region. All the faces are 64x64 pixel size. Fig.3 shows the proposed gender recognition framework. Input image is firstly passed through a preprocessing module and then feature extractors are used for extracting prominent features. Finally, Adaboost classifier has been used for the classification of male and female faces. The detail of proposed framework is described on the following subsections.

### A. Contrast Enhancement

Gender classification from facial images uses different methods to extract several distinctive features such as edge, corner, lines, etc. But sometimes distinctive features may not be clearly displayed due to the existence of noises. As a result, false detection occurs. Thus, elimination of noise is needed before feature extraction.

We have used preprocessing in our proposed framework. Several kinds of image enhancement techniques are available such as Histogram Equalization (HE) [1], Brightness Preserving Bi-Histogram Equalization (BBHE) [26], Exact Histogram Specification (EHS) [21], Recursively Separated and Weighted Histogram Equalization (RSWHE) [27], Locally Transformed Histogram [31], Adaptive Gamma Correction with Weighting Distribution (AGCWD) [2], etc. Among many image enhancement techniques which technique will provide our desired result is a big question due to the existence of drawbacks of image enhancement techniques such as HE sometimes over enhances the image. BBHE fails for non-symmetric distribution. Among all the available image enhancement techniques, we have used AGCWD for enhancing the contrast and reducing noise from an image because of it has some additive advantages.

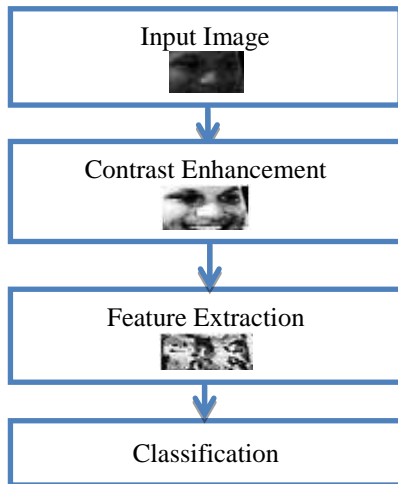

Fig. 3. Proposed gender recognition framework

AGCWD enhances the contrast of an image by using gamma correction. Here, each and every pixel of an image is transformed based on the highest pixel's intensity. As a result, over-enhancement or artifacts will not be occurred [30]. So, we used AGCWD technique for enhancing the contrast and reducing the noise of an image. It enhances the brightness and preserves the available histogram information. Along with this, the algorithm gives more probabilities for infrequent gray levels whereas traditional transformation function does not give more probabilities to the infrequent gray levels [27]. So, infrequent pixel's information is retained. The transformation of the gamma correction (TGC) [2] is defined by (1).

$$T(l) = l_{max} * \left(\frac{l}{l_{max}}\right)^\gamma \tag{1}$$

Where,  $l_{max}$  is the maximum pixel intensity,  $l$  represents each pixel's intensity and  $T(l)$  [2] is a transformed pixel intensity,  $\gamma$  is calculated by (2).

$$\gamma = 1 - cdf_w(l) \tag{2}$$

Here,  $cdf_w$  is the cumulative density function. Fig.4 shows an example of AGCWD.

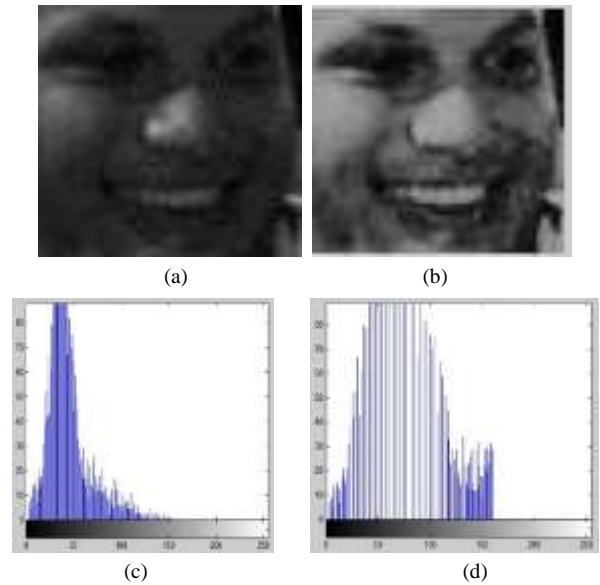

Fig. 4. Contrast enhancement using AGCWD (a) Input image, (b) Image after applying AGCWD, (c) Input image histogram, (d) Output image histogram after applying AGCWD

**B. Feature Extraction**

LBP, LTP, LGP and other feature extractors can effectively describe micro-patterns in facial image. After enhancing contrast of the images using AGCWD, we extracted features from the facial image using LBP, LTP or LGP. The extracted feature histogram describes the local texture and global shape of face images. The basic concept of LBP, LTP and LGP are presented below. Ojala *et al.* [22] introduced basic LBP which defines the basic structure of an image such as edge, corner, lines, etc. LBP considers  $3 \times 3$  neighborhood of a pixel and the neighbor having pixel value greater or equal to the central pixel value is set as a binary value '1' and the neighbor having pixel value less than the central pixel value is set a binary value '0'. The thresholding function  $T(x)$  is defined by (3) where  $x_i$  and  $c_i$  represent neighboring pixel value and central pixel value accordingly.

$$T(x) = \begin{cases} 1 & \text{if } x_i \geq c_i \\ 0 & \text{otherwise} \end{cases} \tag{3}$$

Then binary values of corresponding 8 neighbors are converted to a decimal value and assign it as the new central pixel value. The new central pixel value is calculated by (4).

$$LBP(x_c, y_c) = \sum_{i=0}^7 T(i) \times 2^i \tag{4}$$

Where  $(x_c, y_c)$  is the location of central pixel and  $T(i)$  is the binary value of  $i^{th}$  neighbor. Fig.5 demonstrates basic LBP where central pixel value is 12, binary value is 01110000 and corresponding decimal value is 112.

Fig. 5. LBP of  $3 \times 3$  neighborhood (a)  $3 \times 3$  pixel matrix, (b)  $3 \times 3$  binary value

Tan *et al.* introduced local ternary pattern (LTP) [25] for face recognition which also used 3×3 neighborhood. In LTP, neighbors having pixel value greater than or equal to +5 from the central pixel value is assigned a value '+1', less than or equal to -5 from the central pixel value is assigned as a value '-1', otherwise assigned a value '0'. Here, the thresholding function  $T(i)$  is defined by (5) where  $c_i$ ,  $x$  represents center and neighboring pixels respectively. Fig.6 demonstrates LTP where central pixel is 12.

$$T(i) = \begin{cases} +1 & \text{if } (x - c_i) \geq +5 \\ -1 & \text{if } (x - c_i) \leq -5 \\ 0 & \text{otherwise} \end{cases} \quad (5)$$

Fig.6. LTP of 3×3 neighborhood (a) 3×3 pixel matrix, (b) 3×3 ternary values (c) 3×3 binary values

The LGP was introduced by Jun *et al.* [24] where 3×3 neighborhood of a pixel is considered and the neighbor having gradient greater or equal to the average of eight neighboring gradients is set a binary value '1', otherwise is assigned a binary value '0'. The threshold function is defined by (6)

$$T(x) = \begin{cases} 1 & \text{if } x_g \geq \mu_g \\ 0 & \text{otherwise} \end{cases} \quad (6)$$

Where  $x_g$  is the neighboring gradient and  $\mu_g$  is the average gradient. Fig.7 demonstrates basic LGP where average value is 4, binary value is 01000000 and corresponding decimal value is 64.

Fig.7. LGP of 3×3 neighborhood (a) 3×3 pixel matrix, (b) 3×3 gradient matrix (c) 3×3 binary matrix

After extracting the features using any of the aforementioned feature extractors, we calculated the histogram of those features which can be used as feature or pattern descriptor. We divided the whole image into several non-intersecting sub-blocks to calculate the shape information. Fig.8 illustrates an example of 8×8 blocked facial image and its histogram.

Fig.8. Sub-regions of 8×8 blocks

### C. Classification

After generating feature histogram using feature descriptors such as LBP, LTP or LGP etc, we need to make classification decision depending on those features. For this purpose, Adaboost classifier is employed which dynamically boosts a sequence of weak classifiers considering the errors in previous learning [23] and produce a strong classifier. The boosting is performed by (7).

$$H(x) = \sum_{t=1}^T \alpha_t h_t(x) \quad (7)$$

Where  $\alpha_t$  and  $h_t(x)$  represents boosting coefficient and weak classifier accordingly. We have used Tieu and Viola's adjusted Adaboost algorithm for classification purpose.

## III. EXPERIMENT

This section presents extensive experiments which include experimental settings and description of dataset, training and testing procedure, experimental results and comparisons with other state of the art methods. These are described in the following subsections:

### A. Experimental Settings

We used LFW database for our experimental purpose [17]. LFW is a database for studying the problem of real life gender recognition, which consists of 13,230 facial images of 5,749 subjects (4,263 male, 1,486 female) collected from the web. Images are also gender imbalanced, which contains 10,255 male and 2,975 female samples. We divided the data set into five similar sizes, keeping the same number of female and male sample in each division. Fig.9 presents few sample images of LFW database which are captured in uncontrolled situation.

### B. Training and Testing

We have applied AGCWD before features extraction. Five folds cross-fold validations have been performed in each case. Therefore four parts containing 10,584 facial images are used for training and the remaining 2,646 facial images are used for test and this process is repeated five times for all the methods. Adaboost is used for feature selection and classification. The top five hundred features are selected using adaboost for training and testing purpose.

Fig. 9. Few sample male and female images from LFW database. First, third rows presents male and second, fourth rows presents female facial images.

C. Experimental Result

To evaluate the performance of proposed framework, we have used True Positive Rate (TPR), False Positive Rate (FPR), and overall accuracy by equation (8), (9) and (10) respectively to demonstrate the performance.

$$TPR = \frac{\text{Male correctly classified}}{\text{Total male}} \tag{8}$$

$$FPR = \frac{\text{Female incorrectly classified}}{\text{Total female}} \tag{9}$$

$$\text{accuracy} = \frac{TP+TN}{TP+TN+FN+FP} \times 100\% \tag{10}$$

Where TP indicates true positive, which represents a positive value that the system has recognized as positive, TN stands for true negative that the system identifies as negative which is actually negative, FP is false positive which predicts as positive though it is negative and FN is false negative which identifies positive though it is negative. Accuracy is defined as the ratio of the number of gender correctly classified to the total number of gender. Besides this to illustrate the results more extensively we adopt Precision, Recall and F-measure which are defined by equation (11), (12) and (13) respectively.

$$\text{Precision} = \frac{TP}{TP+FP} \tag{11}$$

$$\text{Recall} = \frac{TP}{TP+FN} \tag{12}$$

$$F_{\text{measure}} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{13}$$

F-measure [16] is used as an evaluation metric for measuring regression performance of our proposed framework. It is the harmonic mean of precision and recall. The large value of F-measure indicates higher classification quality. This system has been experimented over 10,255 male and 2,975 female faces.

Beside these, 3 confusion matrixes are created for evaluating the performance of the proposed system as

well as comparing with other existing systems. Confusion matrix allows visualizing the performance of a proposed method in a supervise learning. Table 2, Table 3, Table 4 present the confusion matrix of gender recognition using LBP, LTP and LGP respectively which contain the recognition result using preprocessing (AGCWD) and without preprocessing.

Table 2. Confusion matrix for gender recognition without and with preprocessing in LBP

|        | LBP   |        | LBP + Preprocessing |              |
|--------|-------|--------|---------------------|--------------|
|        | Male  | Female | Male                | Female       |
| Male   | 9,747 | 508    | <b>9,797</b>        | 458          |
| Female | 784   | 2,191  | 745                 | <b>2,230</b> |

Table 2 illustrates that using only LBP 9,747 male and 2,191 female are correctly detected. 508 male faces and 784 female faces are misclassified. On the other hand, LBP with proposed method can recognize 9,797 male and 2,230 female correctly. 458 male and 745 female are misclassified by proposed method.

Table 3. Confusion matrix for gender recognition without and with preprocessing in LTP

|        | LTP   |        | LTP + Preprocessing |              |
|--------|-------|--------|---------------------|--------------|
|        | Male  | Female | Male                | Female       |
| Male   | 9,764 | 491    | <b>9,805</b>        | 450          |
| Female | 783   | 2,192  | 731                 | <b>2,244</b> |

From Table 3, it is clear that LTP can correctly detect 9,764 male and 2,192 female. 491 male and 783 female faces are wrongly detected. On the other hand, LTP with preprocessing can recognize 9,805 male and 2,244 female accurately. 450 female and 731 male face images are misclassified by proposed technique.

Table 4. Confusion matrix for gender recognition without and with preprocessing in LGP

|        | LGP   |        | LGP + Preprocessing |              |
|--------|-------|--------|---------------------|--------------|
|        | Male  | Female | Male                | Female       |
| Male   | 9,696 | 559    | <b>9,740</b>        | 515          |
| Female | 849   | 2,126  | 803                 | <b>2,172</b> |

Table 4 represents that LGP can accurately detect 9,696 male and 2,126 female. On the contrary, LGP with preprocessing can recognize 9,740 male and 2,172 female accurately. 559 male were misclassified by using only LGP whereas 515 male misclassified by using preprocessing before LGP. Female recognition is also improved by our method in LGP.

From the above confusion matrices, in a nutshell it can be said that female recognition rate is not as satisfactory as expected by existing methods. One of the major reasons behind it is that the textures of the facial images are not properly visible. This can be easily understandable by Fig.10. Further the male image in LFW database is significantly large with compare to number of female facial images. This might also affect the result. However, when we incorporate our method, female recognition rate has been increased. So, it can be

concluded that recognition performance of LBP, LTP and LGP is increased after applying the preprocessing technique which is based on AGCWD.

(b)  
Fig. 10. Incorrectly recognized by existing approach but correctly recognized by the proposed approach. (a) Original image, (b) Images after applying proposed preprocessing

Table 5, Table 6, Table 7 present the accuracy, precision, recall and F-measure for each folder using LBP, LTP and LGP without and with preprocessing respectively.

Table 5. Performance Analysis of Proposed Gender Recognition Technique (LBP)

| Fold        | Accuracy (%) |              | Precision |              | Recall |              | F-measure |              |

| <b>Avg.</b> | 89.36        | <b>90.04</b> | 0.919     | <b>0.924</b> | 0.945  | <b>0.950</b> | 0.932     | <b>0.937</b> |

From the above tables and discussion, it is clear that after applying the proposed preprocessing in LBP, LTP and LGP, the rate of accuracy and the value of F-measure have increased. As the value of accuracy and F-measure is increased in our proposed framework, it can be concluded that our proposed framework performs superior on existing state-of-the-art methods.

Fig.11. Accuracy (%) of different techniques

Table 8 presents TPR and FPR of LBP, LTP, and LGP with preprocessing and without preprocessing True positive rate and false positive rate are calculated by equations (8) and (9) respectively. Higher value of TPR and lower value of FPR indicates higher recognition accuracy.

Table 8. TPR and FPR of Proposed Method using LBP, LTP and LGP

| Feature Types | TPR           |               | FPR           |               |
|---------------|---------------|---------------|---------------|---------------|
|               | Without Prep. | With Prep.    | Without Prep. | With Prep.    |
| Basic LBP     | .95046        | <b>.95534</b> | .26352        | <b>.25042</b> |
| LTP           | .95212        | <b>.95612</b> | .26319        | <b>.24571</b> |
| LGP           | .94549        | <b>.94978</b> | .28538        | <b>.26992</b> |

From Table 8, we can see that TPR has increased by using preprocessing before LBP, LTP, and LGP. On the contrary, FPR has decreased for using preprocessing before LBP, LTP, and LGP. So, from TPR and FPR it can also be summarized that our proposed framework performs superior than existing techniques. Fig.12 and Fig.13 plot the result of TPR and FPR respectively.

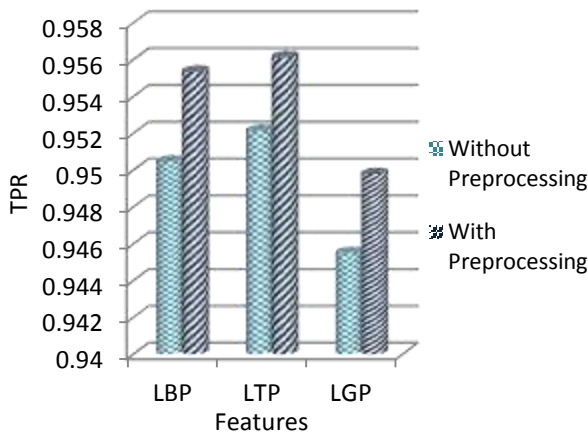

Fig. 12. TPR of different techniques

#### D. Discussion

From Table 2-8 and Fig.10-13, it is clear that by adopting a suitable preprocessing technique this research has increased the rate of accuracy, precision, recall and F-measure than running state-of-art gender recognition methods. In real life images several kinds of noises may exist due to lack of illumination, quality of the image capturing devices, or presence of the cloud, etc. As a result, prominent features cannot be effectively extracted from the facial images. For getting distinguished features from images, it is needed to increase the brightness and contrast of the images as well. We have tried to choose a better preprocessing technique to improve the performance of gender recognition technique. The main reason of our superiority is that we have adopted AGCWD contrast enhancement technique which does not over enhance an image and also reduce the noises.

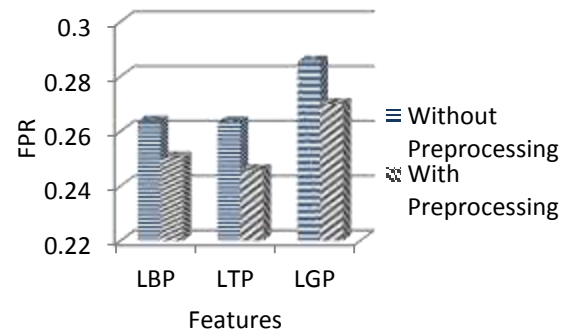

Fig.13. FPR of different techniques

It also avoids the generation of unfavorable artifacts. Over enhancement and generating artifacts are the major problems in traditional image enhancement methodology which reduces the performance rate. So, by using effective preprocessing technique our proposed gender recognition method performs superior than other existing eminent methods which are based on LBP, LTP or LGP.

#### IV. CONCLUSION

In this paper, we have reviewed state-of-the-art gender recognition techniques. All of these methods show competitive results and perform reasonably well. However, in case of illumination problem they might fail which can be easily elevated with an image enhancement technique as a preprocessing step. This is demonstrated in detail in our experimental section. Our proposed method enhanced the images and existing feature extraction such as LBP, LTP or LGP are implemented on the preprocessed images. Cross validation is applied on LFW dataset to test the results and it provides that the proposed method works better than existing gender recognition methods. It is well known that illumination and pose variations are the major problems in case of feature based holistic approaches. In this paper, we address the illumination problem. A more sophisticated image preprocessing technique along with a dynamic size block for adopting pose variation can further improve the overall accuracies which we will address in future.

#### Authors' Profiles

processing and software engineering etc.

engineering etc.

**Md. Mostafijur Rahman** is currently (2014) an undergraduate student of Institute of Information Technology, University of Dhaka, Bangladesh. His current research interests include digital image processing, facial image analysis, face, gender, expression recognition, feature extraction, face detection, machine learning, video processing and software engineering etc.

**Shanto Rahman** is currently (2014) an undergraduate student of Institute of Information Technology (IIT), University of Dhaka, Bangladesh. Her current research interests in image processing, gender recognition, image enhancement, digital image, video processing and software

**Emon Kumar Dey** received his M.S degree in Computer Science and Engineering from University of Dhaka, Bangladesh in 2011. Currently he is a Lecturer of Institute of Information Technology, University of Dhaka, Bangladesh. His research interest include image processing, pattern recognition,

machine learning, computer vision, data mining and software engineering.

**Mohammad Shoyaib** received his M.Sc. degree in computer science from the University of Dhaka, Bangladesh, in 2000 and in 2012. He has completed his PhD degree from the department of computer Engineering, Kyung Hee University, South Korea. Currently he is a faculty member of Institute of Information Technology,

University of Dhaka, Bangladesh. His research interests include pattern recognition and machine learning in different areas of computer vision and image processing. He has also interest in software engineering and bioinformatics
